HXC-001 — CONST-052 owned-org directory rename: COMPLETE (no in-scope dirs remain)

Operator authorized “rename parent org-dirs to lowercase”. Investigation (subagent, §11.4.6 investigate-before-touch): - ZERO non-lowercase owned-org parent/grouping DIRECTORIES on disk. The rename programme (46 PascalCase leaf dirs + HelixDevelopment/ parent) is ALREADY COMPLETE in the live tree: flat lowercase submodules/, every consumer go.mod replace already points there, dependencies/ holds only the 3 exempt third-party (HuggingFace_Hub/LLama_CPP/Ollama). - Verification (captured): verify-governance-cascade.sh → 0 failures; git submodule status uninitialized count → 0; consumer go.mod replace dirs pointing into dependencies/{vasic-digital,HelixDevelopment}/ → 0; PascalCase owned leaf dirs on disk → ABSENT. RESIDUAL (out of the “directory rename” scope, NOT done): 57 internal git SECTION-NAME KEYS (.gitmodules/.git/config/ .git/modules) still read dependencies/<Org>/<name>. These are git logical identifiers, not worktree directories, not referenced by any build/import/path. Normalizing them = 4 atomic touchpoints × 57 (rewrite section name + config key + physically move .git/modules storage subtree + rewrite each worktree .git gitdir pointer) — HIGH-RISK (submodule-detachment), ZERO functional benefit. NOT performed autonomously (§11.4.101 block-only-when: irreversible-ish + high-blast-radius + zero-benefit). Needs separate explicit operator authorization for that specific plumbing op if desired. Also flagged: docs/research/const052/rename-plan.md (rev1, round 343) is STALE — describes the now-completed leaf renames as “remaining”.
