

W7D — Root-Level Dead-Code

Disposition: Forensic Verdict + Deletion Plan

Date: 2026-06-04 **Status:** INVESTIGATED + OPERATOR-APPROVED FOR DELETION — execution deferred to next session (continue). **Operator decision (2026-06-04):** “Delete all 5, HOWEVER double-check via git history how we got to these being unused — if we deliberately applied an alternative and left these, OK; but we MUST be careful it is NOT the other way around (that these are the real ones and the alternative is the mistake).”

1. Targets (root meta-repo Go helpers, ~2978 LOC)

- internal/security/ (1526 LOC — manager.go + scanners.go)
- internal/fix/ (885 LOC — security_fixer.go)
- internal/testing/ (567 LOC — security_integration.go)
- internal/theme/ (9 LOC — 5 hex color consts)
- cmd/security-test/ (23 LOC — runtime-disabled logging stub)

2. Supersession-direction forensic (the operator’s “huge mistake” check) — CONCLUSIVE: SAFE TO DELETE ROOT

(A) Live-wiring proves the INNER copies are the real/running code, root has zero live consumers. Both the root meta-repo and inner helix_code/ declare module dev.helix.code (two modules, same path), so inner dev.helix.code/ internal/... imports resolve to the INNER packages. Evidence (grep of helix_code/cmd/): - helix_code/cmd/security_test/main.go:10 imports dev.helix.code/internal/security → INNER. - helix_code/cmd/security_fix/main.go:9 imports dev.helix.code/internal/fix → INNER. - helix_code/cmd/cli/main.go:44 (the **main CLI**) imports dev.helix.code/internal/theme → INNER. - ROOT cmd/security-test/main.go imports NOTHING (go list -deps ./cmd/security-test = only itself; it is the disabled stub). The root internal/{security, fix, testing} form a closed testing→security←fix cluster with **no root cmd/ entry point** reaching them.

(B) Recency confirms inner is forward, root is abandoned. - ROOT internal/security: last touched 062e11f8 2026-05-12 (a compile-fix, NOT a deprecation). - INNER helix_code/internal/security: last touched 31c57a2a 2026-05-29. - ROOT internal/fix + cmd/security-test: stuck at 5fcc5a49 2025-12-11

("Auto-commit") — ~6 months abandoned. - INNER helix_code/internal/fix + cmd/security_test: 2026-05-29. - submodules/security (digital.vasic.security, canonical own-org): 2026-06-03.

(C) The 062e11f8 commit message itself distinguishes them. It repaired root internal/security to make go build ./... pass, explicitly noting it is *"separate from Zero-Bluff P2-T01's HelixCode/internal/security/"* — i.e. the INNER one is the planned/canonical implementation; the root one is the older (2025-11-08-created) separate artifact merely kept compiling.

Conclusion: We are NOT at risk of deleting the real implementation. The real, live, actively-maintained code is the inner (helix_code/internal/*, wired to live entry points incl. the main CLI) + the own-org submodules/security. The root copies are the genuinely-superseded, zero-consumer remnant. Deleting root is the correct direction and removes a CONST-051(B)/(C) own-org-code-duplicated-at-root violation. It is git-reversible (§9.2).

Honest residual (§11.4.6): No go run ./cmd/security-test-by-path invocation found in Makefile/scripts. Execution step below re-runs that sweep once more immediately before git rm.

3. Deletion plan (for next-session continue — execute in order)

1. Final ref-sweep: grep -rn "internal/security\|internal/fix\|internal/testing\|cmd/security-test\|cmd/security_test" Makefile scripts/ .github 2>/dev/null (root-scope only; ignore helix_code/** matches which are the inner module) + grep -rn "go run ./cmd/security-test". Any hit → STOP + re-evaluate.
2. git rm -r internal/security internal/fix internal/testing internal/theme cmd/security-test (root paths only).
3. go build ./... (root module) must still exit 0; go vet ./... clean.
4. Commit + push (github + gitlab). Message cites this doc + the forensic verdict.
5. Update CONTINUATION close-out + this doc's Status → Completed (deleted).
